## Overview of Cavity Ring-Down Spectroscopy (CRDS)

### How CRDS Works

1. A Continuous Wave (CW) laser emits a directed beam of light into a gas cell with two highly reflective mirrors on either end (cavity). The laser wavelength is chosen to be absorbed by the target molecule.
2. The light reflects back and forth between two ultra-high reflective mirrors multiple times, creating a total optical absorption path length of up to 100 kilometers.
3. Once the detector "sees" a sufficient level of light energy built up inside the cavity, the light source is turned off quickly, starting the measurement.
4. On each successive pass, a small amount of light or ring-down signal emits through the second mirror and is sensed by the light detector.
5. This exponential decay, or "ring-down" is recorded and is a direct measure of the losses inside the cavity, which includes the absorption of the target molecule.
6. The CRDS decay constant (ring-down time) is independent of laser fluctuations or external background and provides an absolute and extremely sensitive measurement of the target molecule's concentration.
